2020-03-18

## Instructions

Rubric: {mechanics:5}

**IMPORTANT!!! Before proceeding, please carefully read the general homework instructions at <https://www.cs.ubc.ca/~fwood/CS340/homework/>.** The above 5 points are for following the submission instructions. You can ignore the words “mechanics”, “reasoning”, etc.

We use blue to highlight the deliverables that you must answer/do/submit with the assignment.

## 1 Kernel Logistic Regression

If you run `python main.py -q 1` it will load a synthetic 2D data set, split it into train/validation sets, and then perform regular logistic regression and kernel logistic regression (both without an intercept term, for simplicity). You’ll observe that the error values and plots generated look the same since the kernel being used is the linear kernel (i.e., the kernel corresponding to no change of basis).

### 1.1 Implementing kernels

Rubric: {code:5}

Implement the polynomial kernel and the RBF kernel for logistic regression. Make sure to include the code you have written in your pdf GradeScope submission. Report your training/validation errors and submit the plots generated for each case. You should use the hyperparameters  $p = 2$  and  $\sigma = 0.5$  respectively, and  $\lambda = 0.01$  for the regularization strength.

### 1.2 Hyperparameter search

Rubric: {code:3}

For the RBF kernel logistic regression, consider the hyperparameters values  $\sigma = 10^m$  for  $m = -2, -1, \dots, 2$  and  $\lambda = 10^m$  for  $m = -4, -3, \dots, 0$ . In `main.py`, sweep over the possible combinations of these hyperparameter values. Make sure to include the code you have written in your pdf GradeScope submission. Report the hyperparameter values that yield the best training error and the hyperparameter values that yield the best validation error. Include the plot for each.

Note: on the job you might choose to use a tool like scikit-learn’s `GridSearchCV` to implement the grid search, but here we are asking you to implement it yourself by looping over the hyperparameter values.

### 1.3 Reflection

Rubric: {reasoning:1}

Briefly discuss the best hyperparameters you found in the previous part, and their associated plots. Was the training error minimized by the values you expected, given the ways that  $\sigma$  and  $\lambda$  affect the fundamental tradeoff?

## 2 MAP Estimation

Rubric: {reasoning:8}

In class, we considered MAP estimation in a regression model where we assumed that:

- The likelihood  $p(y_i | x_i, w)$  is a normal distribution with a mean of  $w^T x_i$  and a variance of 1.
- The prior for each variable  $j$ ,  $p(w_j)$ , is a normal distribution with a mean of zero and a variance of  $\lambda^{-1}$ .

Under these assumptions, we showed that this leads to the standard L2-regularized least squares objective function,

$$f(w) = \frac{1}{2} \|Xw - y\|^2 + \frac{\lambda}{2} \|w\|^2,$$

which is the negative log likelihood (NLL) under these assumptions (ignoring an irrelevant constant). For each of the alternate assumptions below, show how the loss function would change (simplifying as much as possible):

1. We use a Laplace likelihood with a mean of  $w^T x_i$  and a scale of 1, and we use a zero-mean Gaussian prior with a variance of  $\sigma^2$ .

$$p(y_i | x_i, w) = \frac{1}{2} \exp(-|w^T x_i - y_i|), \quad p(w_j) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{w_j^2}{2\sigma^2}\right).$$

2. We use a Gaussian likelihood where each datapoint has its own variance  $\sigma_i^2$ , and where we use a zero-mean Laplace prior with a variance of  $\lambda^{-1}$ .

$$p(y_i | x_i, w) = \frac{1}{\sqrt{2\sigma_i^2\pi}} \exp\left(-\frac{(w^T x_i - y_i)^2}{2\sigma_i^2}\right), \quad p(w_j) = \frac{\lambda}{2} \exp(-\lambda|w_j|).$$

You can use  $\Sigma$  as a diagonal matrix that has the values  $\sigma_i^2$  along the diagonal.

3. We use a (very robust) student  $t$  likelihood with a mean of  $w^T x_i$  and  $\nu$  degrees of freedom, and a zero-mean Gaussian prior with a variance of  $\lambda^{-1}$ ,

$$p(y_i | x_i, w) = \frac{\Gamma(\frac{\nu+1}{2})}{\sqrt{\nu\pi}\Gamma(\frac{\nu}{2})} \left(1 + \frac{(w^T x_i - y_i)^2}{\nu}\right)^{-\frac{\nu+1}{2}}, \quad p(w_j) = \frac{\sqrt{\lambda}}{\sqrt{2\pi}} \exp\left(-\lambda\frac{w_j^2}{2}\right).$$

where  $\Gamma$  is the “gamma” function (which is always non-negative).

4. We use a Poisson-distributed likelihood (for the case where  $y_i$  represents counts), and we use a uniform prior for some constant  $\kappa$ ,

$$p(y_i | w^T x_i) = \frac{\exp(y_i w^T x_i) \exp(-\exp(w^T x_i))}{y_i!}, \quad p(w_j) \propto \kappa.$$

(This prior is “improper” since  $w \in \mathbb{R}^d$  but it doesn’t integrate to 1 over this domain, but nevertheless the posterior will be a proper distribution.)

### 3 Principal Component Analysis

Rubric: {reasoning:3}

Consider the following dataset, containing 5 examples with 2 features each:

$x_1$	$x_2$
-4	3
0	1
-2	2
4	-1
2	0

Recall that with PCA we usually assume that the PCs are normalized ( $\|w\| = 1$ ), we need to center the data before we apply PCA, and that the direction of the first PC is the one that minimizes the orthogonal distance to all data points.

1. What is the first principal component?

Answer:

The data has means  $(0, 1)$ . Centering the data,

$x_1$	$x_2$
-4	2
0	0
-2	1
4	-2
2	-1

$x_2 = -0.5x_1$ , and the unit vector  $w_1 = (2/\sqrt{5}, -1/\sqrt{5})$  spans the line.

2. What is the reconstruction loss (L2 norm squared) of the point  $(-3, 2.5)$ ? (Show your work.)

Answer:

Subtracting point  $(-3, 2.5)$  by the means  $(0, 1)$  and multiplying by  $w_1$ ,

$$z = -3(2/\sqrt{5}) + 1.5(-1/\sqrt{5}) = -7.5/\sqrt{5}$$

To reconstruct the point, multiply by  $w_1$  and add the means,

$$\hat{x} = (-7.5/\sqrt{5})(2/\sqrt{5}, -1/\sqrt{5}) + (0, 1) = (-3, 2.5)$$

Since the reconstructed point is the same as the original point, the reconstruction loss is 0.

3. What is the reconstruction loss (L2 norm squared) of the point  $(-3, 2)$ ? (Show your work.)

Answer:

Subtracting point  $(-3, 2)$  by the means  $(0, 1)$  and multiplying by  $w_1$ ,

$$z = -3(2/\sqrt{5}) + 1(-1/\sqrt{5}) = -7/\sqrt{5}$$

To reconstruct the point, multiply by  $w_1$  and add the means,

$$\hat{x} = (-7/\sqrt{5})(2/\sqrt{5}, -1/\sqrt{5}) + (0, 1) = (-2.8, 2.4)$$

The reconstruction loss is  $(-3 - (-2.8))^2 + (2 - 2.4)^2 = 0.2$ .

Hint: it may help (a lot) to plot the data before you start this question.

### 4 PCA Generalizations

#### 4.1 Robust PCA

Rubric: {code:10}

If you run `python main -q 4.1` the code will load a dataset  $X$  where each row contains the pixels from a single frame of a video of a highway. The demo applies PCA to this dataset and then uses this to reconstruct the original image. It then shows the following 3 images for each frame:

1. The original frame.
2. The reconstruction based on PCA.
3. A binary image showing locations where the reconstruction error is non-trivial.

Recently, latent-factor models have been proposed as a strategy for “background subtraction”: trying to separate objects from their background. In this case, the background is the highway and the objects are the cars on the highway. In this demo, we see that PCA does an OK job of identifying the cars on the highway in that it does tend to identify the locations of cars. However, the results aren’t great as it identifies quite a few irrelevant parts of the image as objects.

Robust PCA is a variation on PCA where we replace the L2-norm with the L1-norm,

$$f(Z, W) = \sum_{i=1}^n \sum_{j=1}^d |\langle w^j, z_i \rangle - x_{ij}|,$$

and it has recently been proposed as a more effective model for background subtraction. [Complete the class `pca.RobustPCA`, that uses a smooth approximation to the absolute value to implement robust PCA. Make sure to include the code you have written in your pdf GradeScope submission. Briefly comment on the results.](#)

Note: in its current state, `pca.RobustPCA` is just a copy of `pca.AlternativePCA`, which is why the two rows of images are identical.

Hint: most of the work has been done for you in the class `pca.AlternativePCA`. This work implements an alternating minimization approach to minimizing the (L2) PCA objective (without enforcing orthogonality). This gradient-based approach to PCA can be modified to use a smooth approximation of the L1-norm. Note that the log-sum-exp approximation to the absolute value may be hard to get working due to numerical issues, and a numerically-nicer approach is to use the “multi-quadric” approximation:

$$|\alpha| \approx \sqrt{\alpha^2 + \epsilon},$$

where  $\epsilon$  controls the accuracy of the approximation (a typical value of  $\epsilon$  is 0.0001).

**Answer:** Robust PCA gives better results for removing the cars on the road, and the results are more consistent across frames.

```

class RobustPCA(AlternativePCA):
    def fit(self, X):
        n,d = X.shape
        k = self.k
        self.mu = np.mean(X,0)
        X = X - self.mu
        self.epsilon = 0.0001    # controls accuracy of approximation

        # Randomly initial Z, W
        z = np.random.randn(n*k)
        w = np.random.randn(k*d)

        for i in range(10): # do 10 "outer loop" iterations
            z, f = findMin(self._fun_obj_z, z, 10, w, X, k)
            w, f = findMin(self._fun_obj_w, w, 10, z, X, k)
            print('Iteration %d, loss = %.1f' % (i, f))

        self.W = w.reshape(k,d)

    def compress(self, X):
        n,d = X.shape
        k = self.k
        X = X - self.mu
        # We didn't enforce that W was orthogonal
        # so we need to optimize to find Z
        # (or do some matrix operations)
        z = np.zeros(n*k)
        z,f = findMin(self._fun_obj_z, z, 100, self.W.flatten(), X, k)
        Z = z.reshape(n,k)
        return Z

```

```

def _fun_obj_z(self, z, w, X, k):
    n,d = X.shape
    Z = z.reshape(n,k)
    W = w.reshape(k,d)

    R = np.dot(Z,W) - X
    f = np.sum(np.sqrt(R**2 + self.epsilon))
    g = np.dot(R, W.transpose()) / f
    return f, g.flatten()

def _fun_obj_w(self, w, z, X, k):
    n,d = X.shape
    Z = z.reshape(n,k)
    W = w.reshape(k,d)

    R = np.dot(Z,W) - X
    f = np.sum(np.sqrt(R**2 + self.epsilon))
    g = np.dot(Z.transpose(), R) / f
    return f, g.flatten()

```

## 4.2 Reflection

Rubric: {reasoning:3}

1. Briefly explain why using the L1 loss might be more suitable for this task than L2.  
Answer: Using the L1 loss gives robustness to outliers, which relates to the cars in the video. Thus, a better background image can be generated, giving better results for the background subtraction.
2. How does the number of video frames and the size of each frame relate to  $n$ ,  $d$ , and/or  $k$ ?  
Answer:  $n$  relates to the number of video frames, and  $d$  relates to the size of each frame in pixels.
3. What would the effect be of changing the threshold (see code) in terms of false positives (cars we identify that aren't really there) and false negatives (real cars that we fail to identify)?  
Answer: Increasing the threshold would give less false positives, but more false negatives.

## 5 Very-Short Answer Questions

Rubric: {reasoning:11}

1. Assuming we want to use the original features (no change of basis) in a linear model, what is an advantage of the "other" normal equations over the original normal equations?  
Answer: The "other" normal equations are faster than the original normal equations if  $n \ll d$ .
2. In class we argued that it's possible to make a kernel version of  $k$ -means clustering. What would an advantage of kernels be in this context?  
Answer: Kernels allow for non-convex clusters.
3. In the language of loss functions and regularization, what is the difference between MLE and MAP?  
Answer: MAP has regularizers while MLE does not.

4. What is the difference between a generative model and a discriminative model?  
 Answer: Discriminative models do not model the features while generative models do.
5. With PCA, is it possible for the loss to increase if  $k$  is increased? Briefly justify your answer.
6. What does “label switching” mean in the context of PCA?  
 Answer: Factors can be rotated with the same result.
7. Why doesn't it make sense to do PCA with  $k > d$ ?  
 Answer:  $k = d$  already gives zero error.
8. In terms of the matrices associated with PCA ( $X, W, Z, \hat{X}$ ), where would an “eigenface” be stored?  
 Answer: An “eigenface” would be stored as a row of  $W$ .
9. What is an advantage and a disadvantage of using stochastic gradient over SVD when doing PCA?  
 Answer: Stochastic gradient is faster than SVD for large datasets, but SVD gives an exact answer.
10. Which of the following step-size sequences lead to convergence of stochastic gradient to a stationary point?
  - (a)  $\alpha^t = 1/t^2$ .
  - (b)  $\alpha^t = 1/t$ .
  - (c)  $\alpha^t = 1/\sqrt{t}$ .
  - (d)  $\alpha^t = 1$ .
 Answer: (b) and (c) will lead to convergence of stochastic gradient to a stationary point.
11. We discussed “global” vs. “local” features for e-mail classification. What is an advantage of using global features, and what is advantage of using local features?  
 Answer: Global features allow for prediction for new users, while local features allow for personalised predictions for specific users.
